# Outline

## Superconductors: 100 Year History

---

### Part I: Pseudogap in cuprates:

- Competing or collaborating?  
(introduction to scanning tunneling microscopy)
  - Nanoscale inhomogeneity: energy & charge modulation  
→ **what is the hidden variable??**
  - Previous studies of chemical disorder  
→ **hidden variable remains mysterious...**
  - STM imaging of oxygen dopants & vacancies  
→ **we found the hidden variable!!**
- 

### Part II: Vortex pinning in iron-based superconductors:

- MFM imaging of  $\text{NdFeAsO}_{1-x}\text{F}_x$ , in-plane anisotropy
- Single atoms → collective pinning

# Outline

- Single atoms → collective pinning

# 101 Years Ago: Discovery of Superconductivity

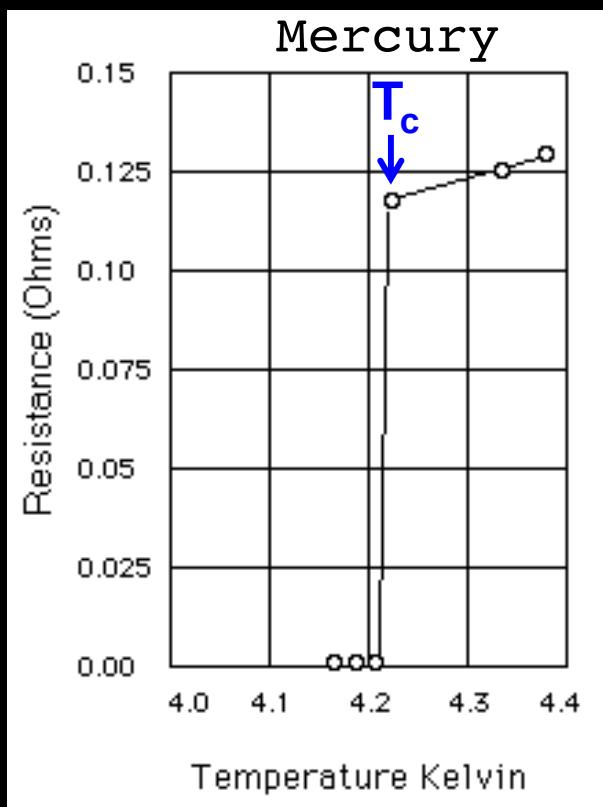

Heike Kamerlingh Onnes (right) and Gerrit Flim, his chief technician, at the helium liquefier in Kamerlingh Onnes's Leiden laboratory, circa 1911.

*Physics Today, Sept 2010*

(101 years later... funding for helium liquefier at Harvard!)

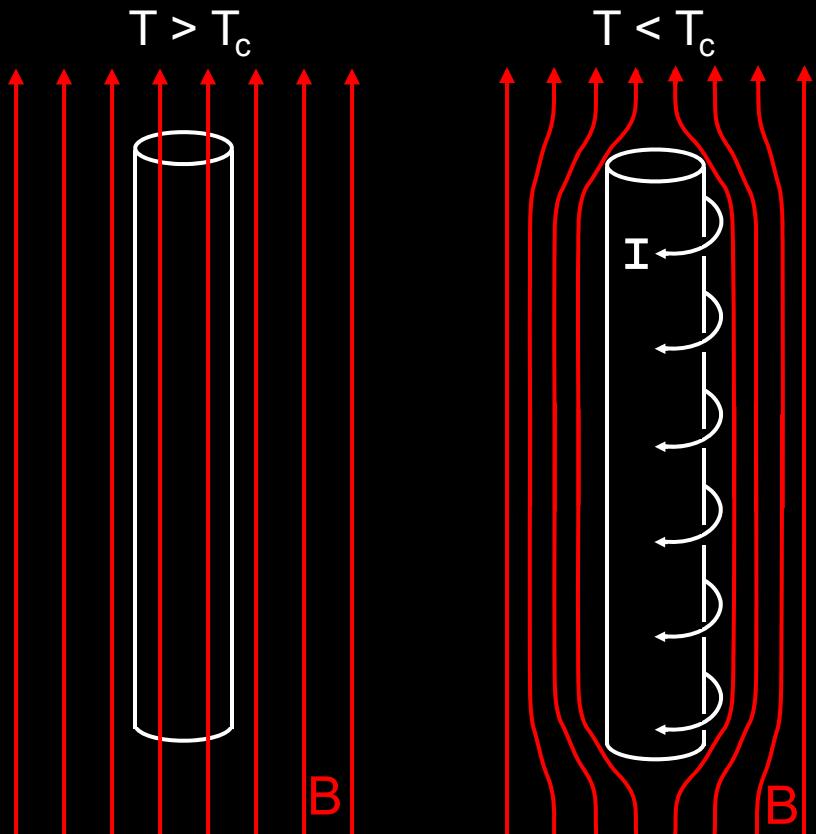

# 2 Properties of Superconductors

1. Vanishing of electrical resistivity  
(by Cooper pairing)

Kamerlingh-Onnes, 1911

2. Expulsion of magnetic field  
(by shielding currents)

Meissner, 1933

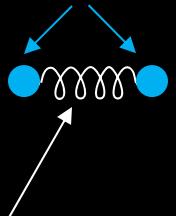

Today's frontiers:

1. Understand pairing → increase  $T_c$

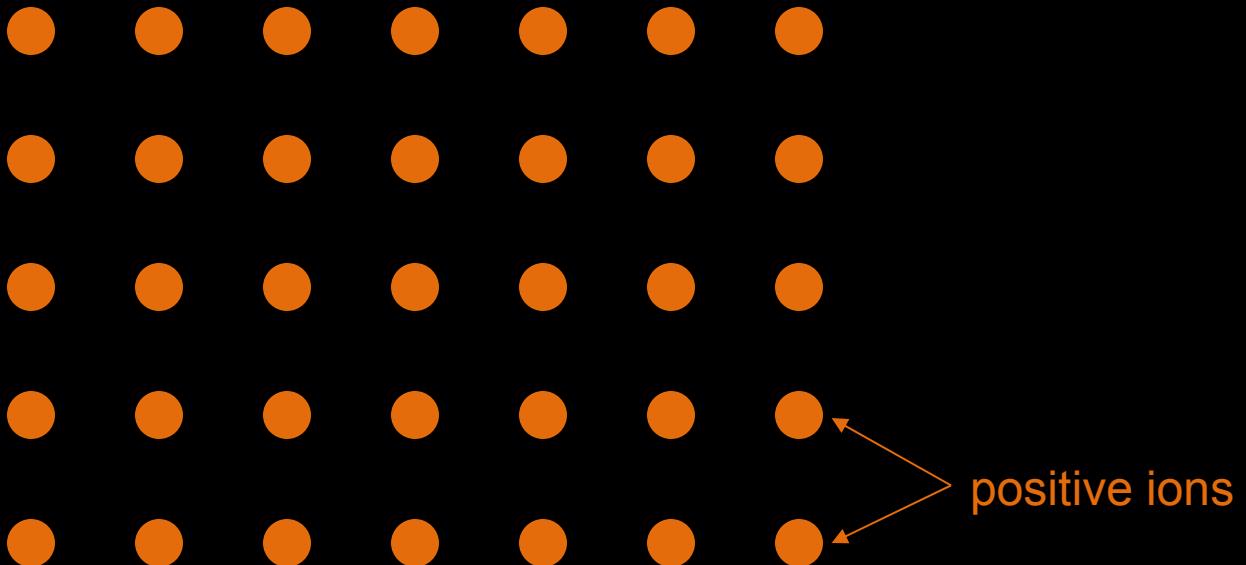

2. Improve magnetic flux pinning

# Cooper pairing

# Bardeen-Cooper-Schrieffer Theory

negative  
electrons form  
“Cooper pairs”

Cooper, *Phys. Rev.* 104, 1189 (1956)

BCS formula:  $k_B T_c = 1.13 \hbar \omega_D e^{\frac{-1}{N(\varepsilon_F)V}}$

$\omega_D$  ~ Debye frequency = highest energy phonon

$V$  ~ electron-phonon coupling

$N(\varepsilon_F)$  = density of states at the Fermi level  
= electrons available for pairing

Bardeen, Cooper, Schrieffer, *Phys. Rev.* 108, 1175 (1957)

# Discovery of cuprate high- $T_c$ superconductors

$$\text{BCS formula: } k_B T_c = 1.13 \hbar \omega_D e^{\frac{-1}{N(\varepsilon_F)V}}$$

$\omega_D$  ~ Debye frequency = highest energy phonon

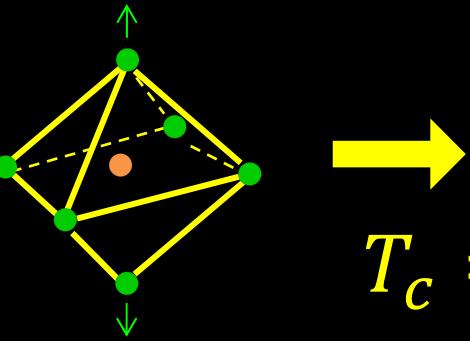

$V$  ~ electron-phonon coupling

$N(\varepsilon_F)$  = density of states at the Fermi level  
= electrons available for pairing

Bardeen, Cooper, Schrieffer, Phys. Rev. 108, 1175 (1957)

Müller's good idea: increase  $V$  by the Jahn-Teller effect

CuO<sub>6</sub> octahedron:

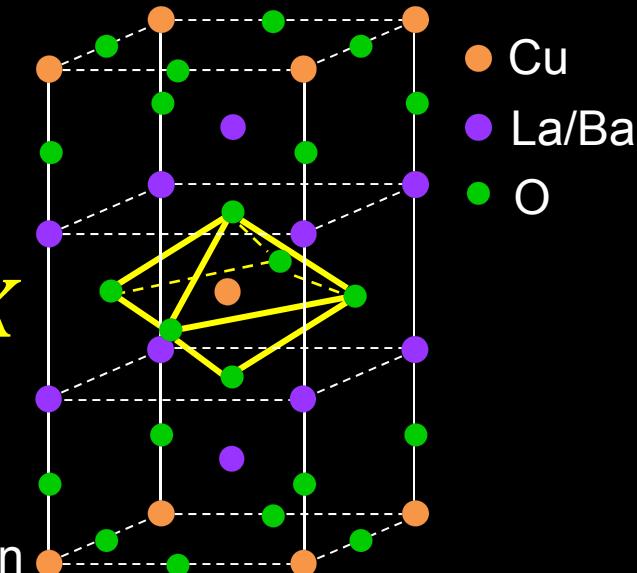

$$T_c = 35 \text{ K}$$

Cu d<sup>9</sup> has 3 e<sup>-</sup> in 2 degenerate e<sub>g</sub> orbitals

→ distorts to lift degeneracy

→ strong electron-phonon coupling via polaron formation

Bednorz & Müller, Zeitschrift für Physik B 64, 189 (1986)

# Isotope effect in cuprates?

$$\text{BCS formula: } k_B T_c = 1.13 \hbar \omega_D e^{\frac{-1}{N(\varepsilon_F)V}}$$

$\omega_D$  ~ Debye frequency = highest energy phonon

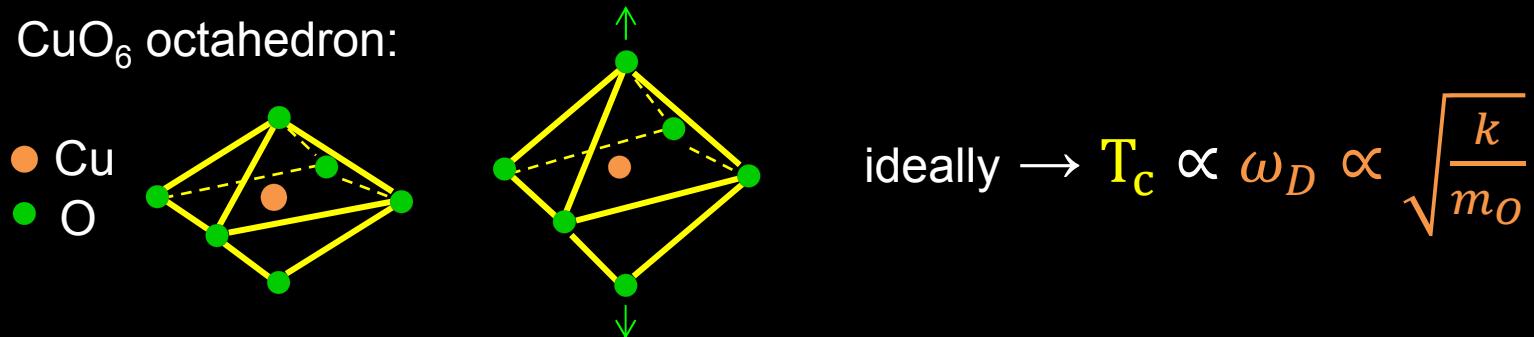

$V$  ~ electron-phonon coupling

$N(\varepsilon_F)$  = density of states at the Fermi level  
= electrons available for pairing

*Bardeen, Cooper, Schrieffer, Phys. Rev. 108, 1175 (1957)*

Test phonon idea: try to modify  $\omega_D$  by  $^{16}\text{O} \rightarrow ^{18}\text{O}$  substitution

CuO<sub>6</sub> octahedron:

$$\text{ideally } \rightarrow T_c \propto \omega_D \propto \sqrt{\frac{k}{m_O}}$$

- experiment: apical O isotope effect is negligible [Zech, *Nature* 371, 681 (1994)]
- phonon mechanism falls out of favor for high-T<sub>c</sub>
- apical oxygens mostly forgotten... (*stay tuned*)

# Cuprate Phase Diagram

# Much evidence: PG competes with SC

Theory:

Experiment:

Other work (global PG competition):

Pushp, *Science* 324, 1689 (2009)

Kondo, *Nature* 457, 296 (2009)

Our preliminary work (local PG competition):

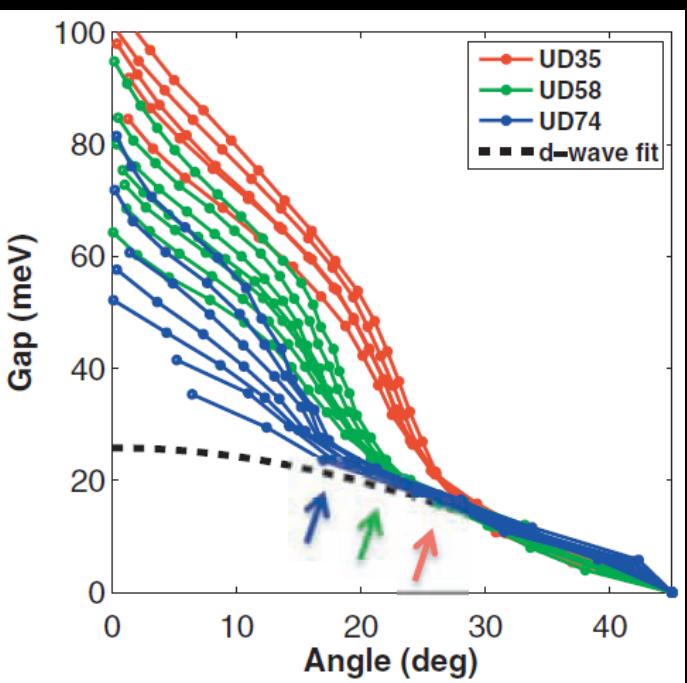

Strong PG regions ( $\Delta_{\text{PG}} > 10\text{meV}$ ): no d-wave coherence

Weak PG regions ( $\Delta_{\text{PG}} < 10\text{meV}$ ): d-wave coherence

Yang He

# Relationship Between PG and SC ?

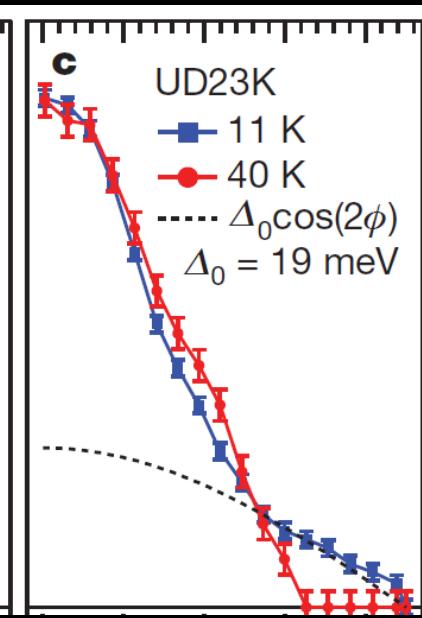

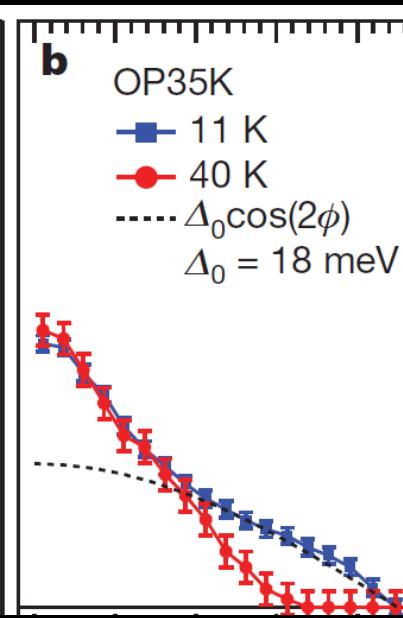

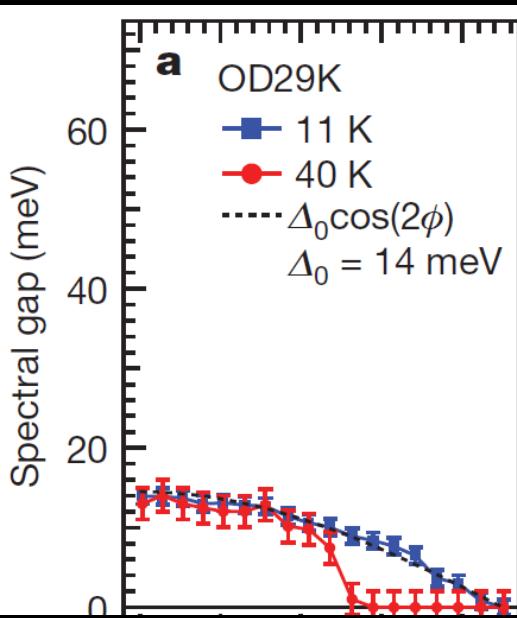

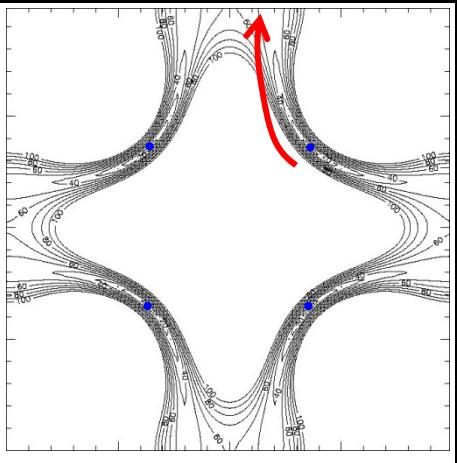

← STM

Pushp, Science 324, 1689 (2009)

STM and ARPES both show competition between superconductivity (wins in nodal region) & pseudogap (wins in antinodal region)

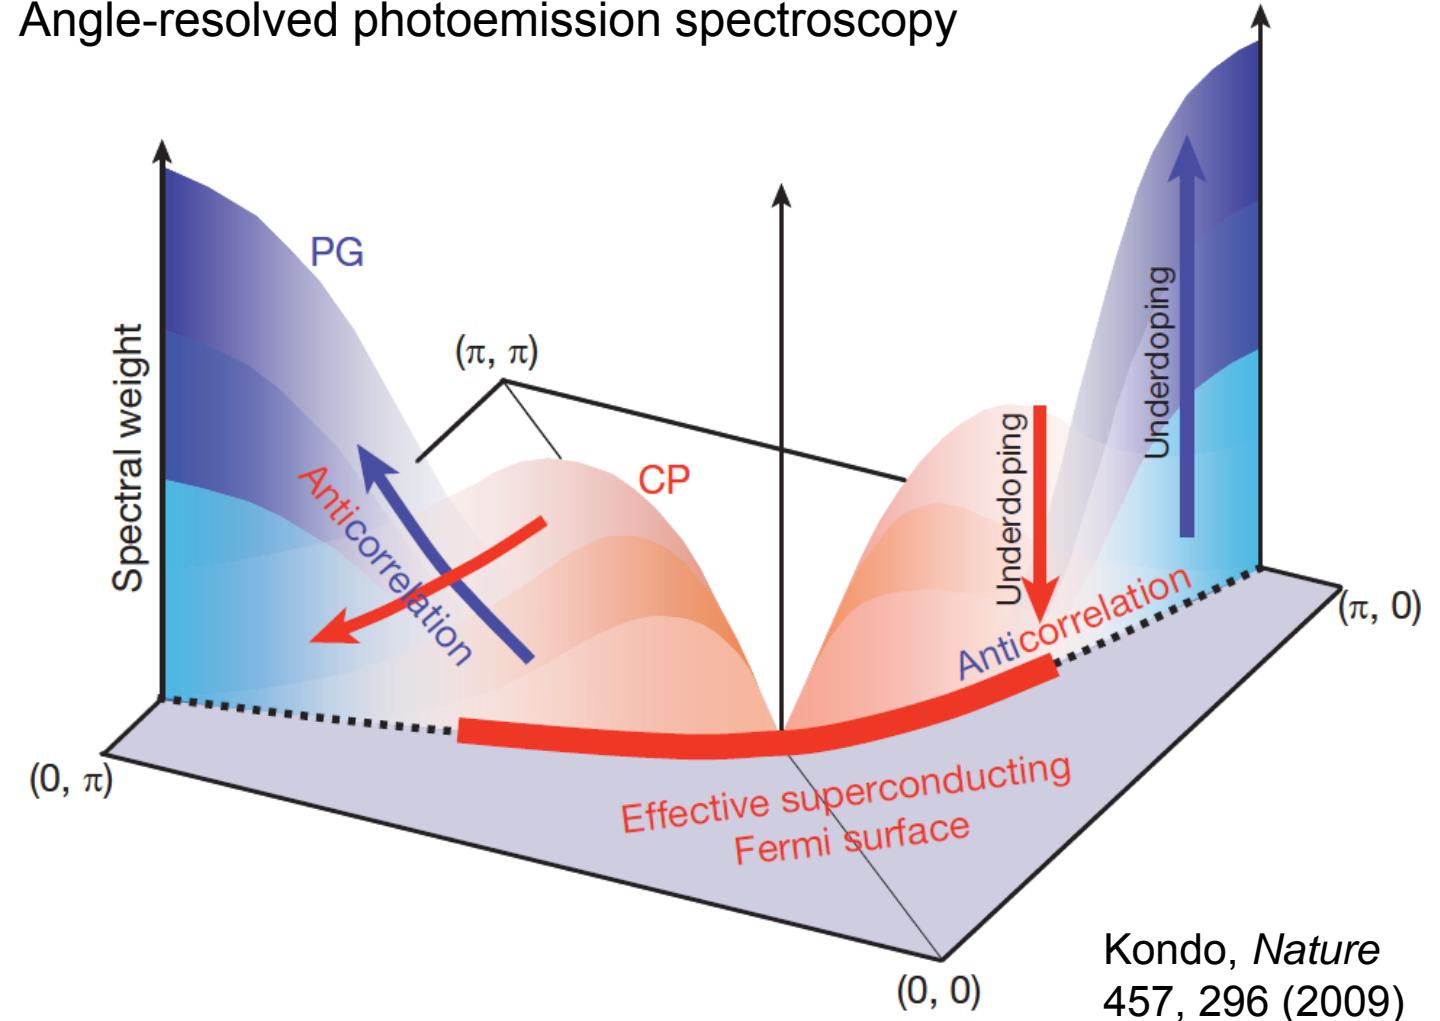

↓ ARPES

Kondo, Nature 457, 296 (2009)

# Competition Between PG and SC

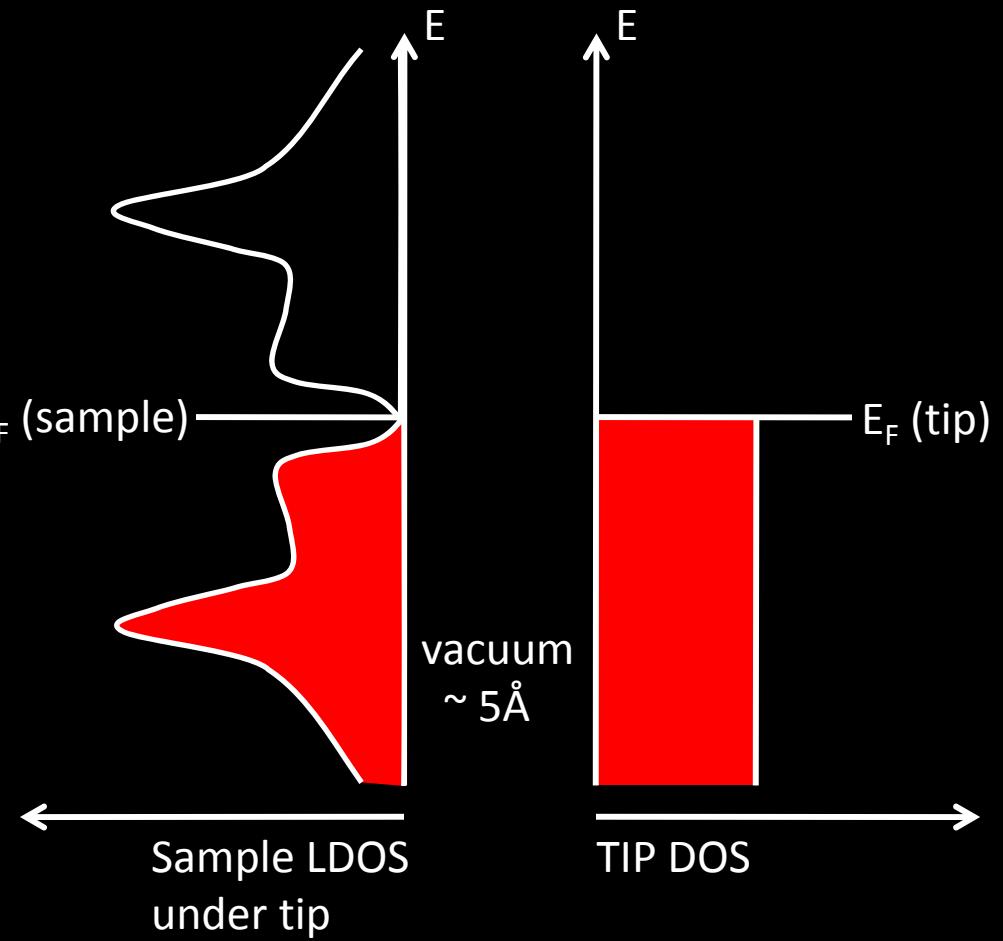

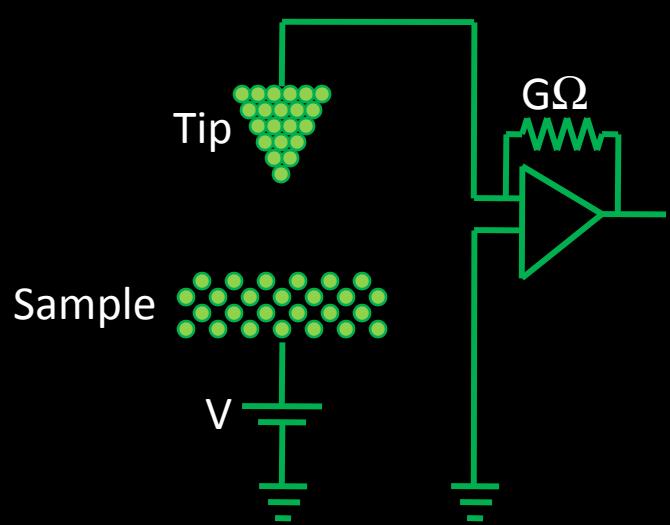

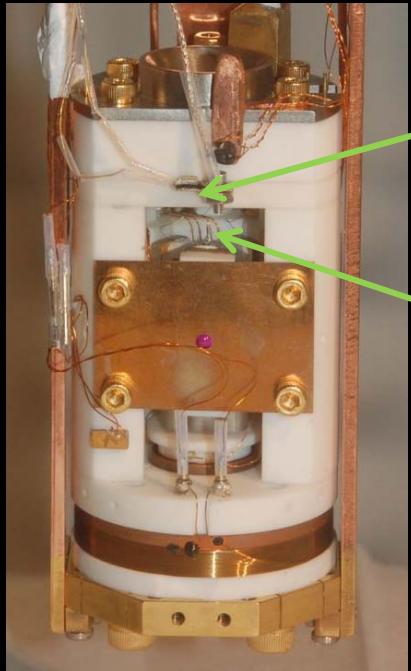

Angle-resolved photoemission spectroscopy

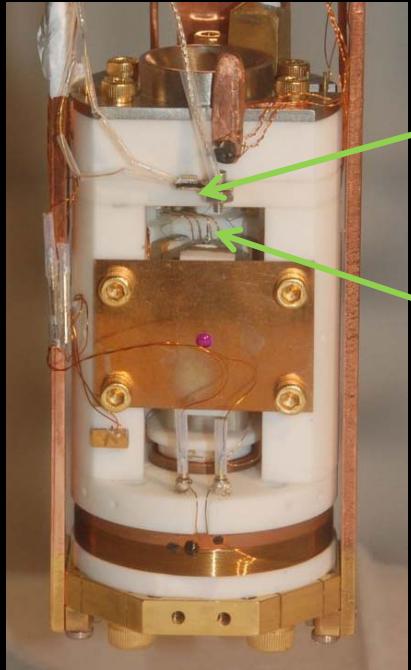

→ We want to know more about the PG  
so we can control it & mitigate the competition!!

No obvious long-range order → use real space probe → STM

### Part II: Vortex pinning in pnictides:

- Discovery of iron-based superconductors
- MFM imaging of NdFeAsO<sub>x</sub>, in-plane anisotropy

# Chemical disorder is crucial to Tc

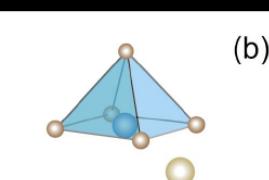

A-site disorder:  
( $\text{Bi}^{3+}$  on  $\text{Sr}^{2+}$  site)  
strongly couples  
to apical oxygen

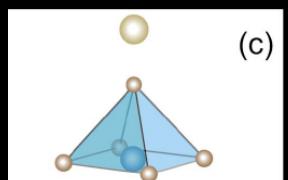

(a)

B-site disorder:  
( $\text{Y}^{3+}$  on  $\text{Ca}^{2+}$  site)  
does not couple  
to apical oxygen

(b)

interstitial O in  $\text{BiO}$  plane  
weakly couples to  $\text{CuO}_2$   
provides charge carriers  
but little disorder  
→ “type-B oxygen”

(c)

# Chemical disorder: location matters

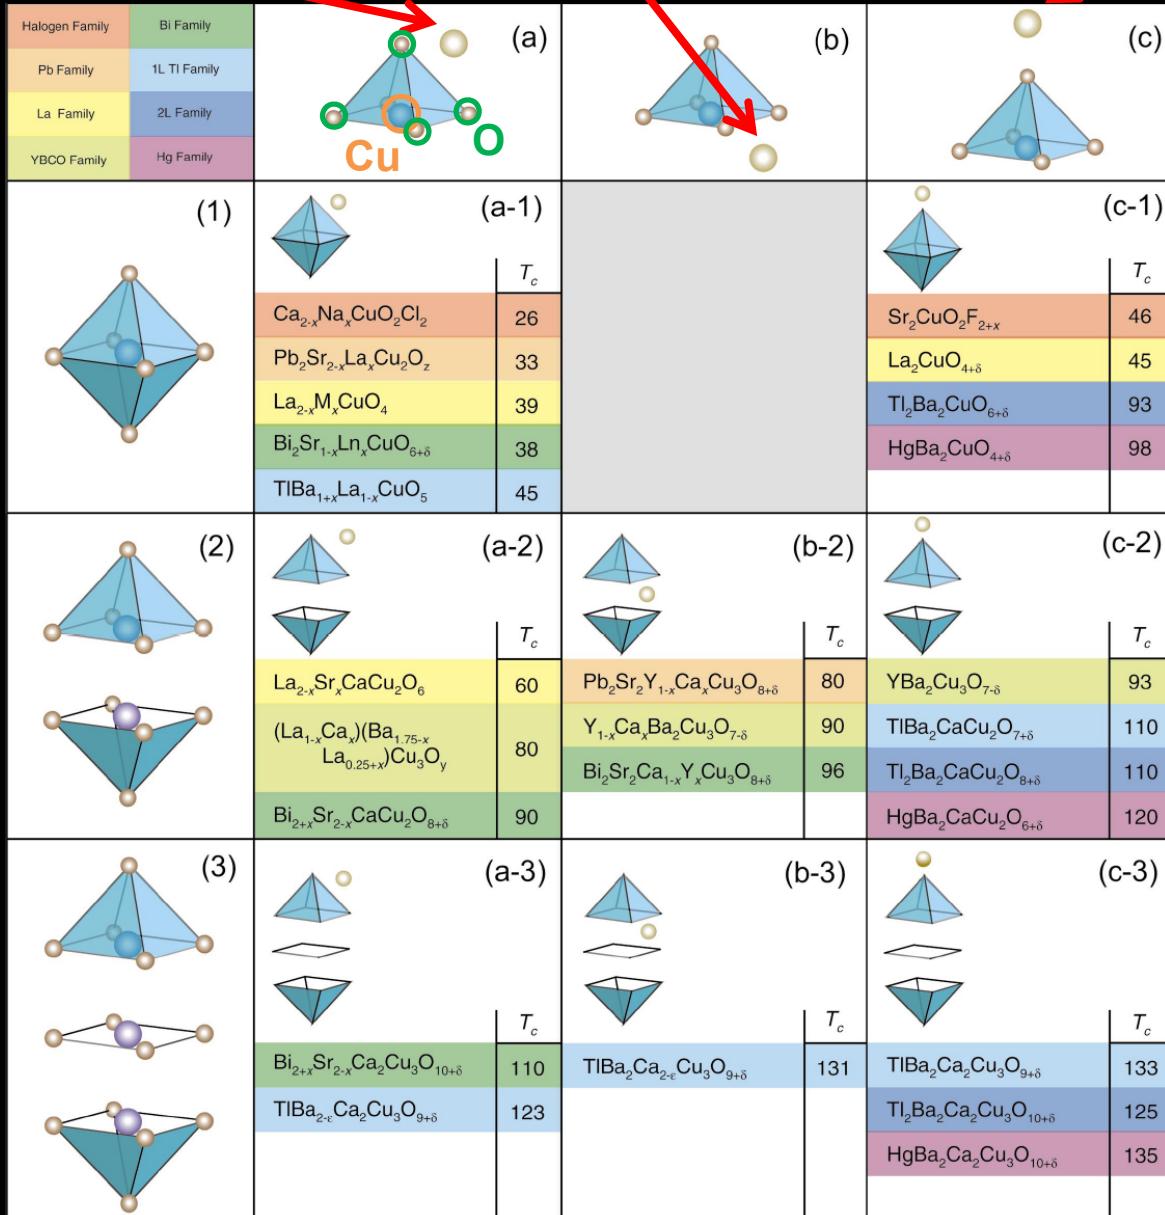

A-site disorder      B-site disorder      interstitial O near B-site

Inference from transport:

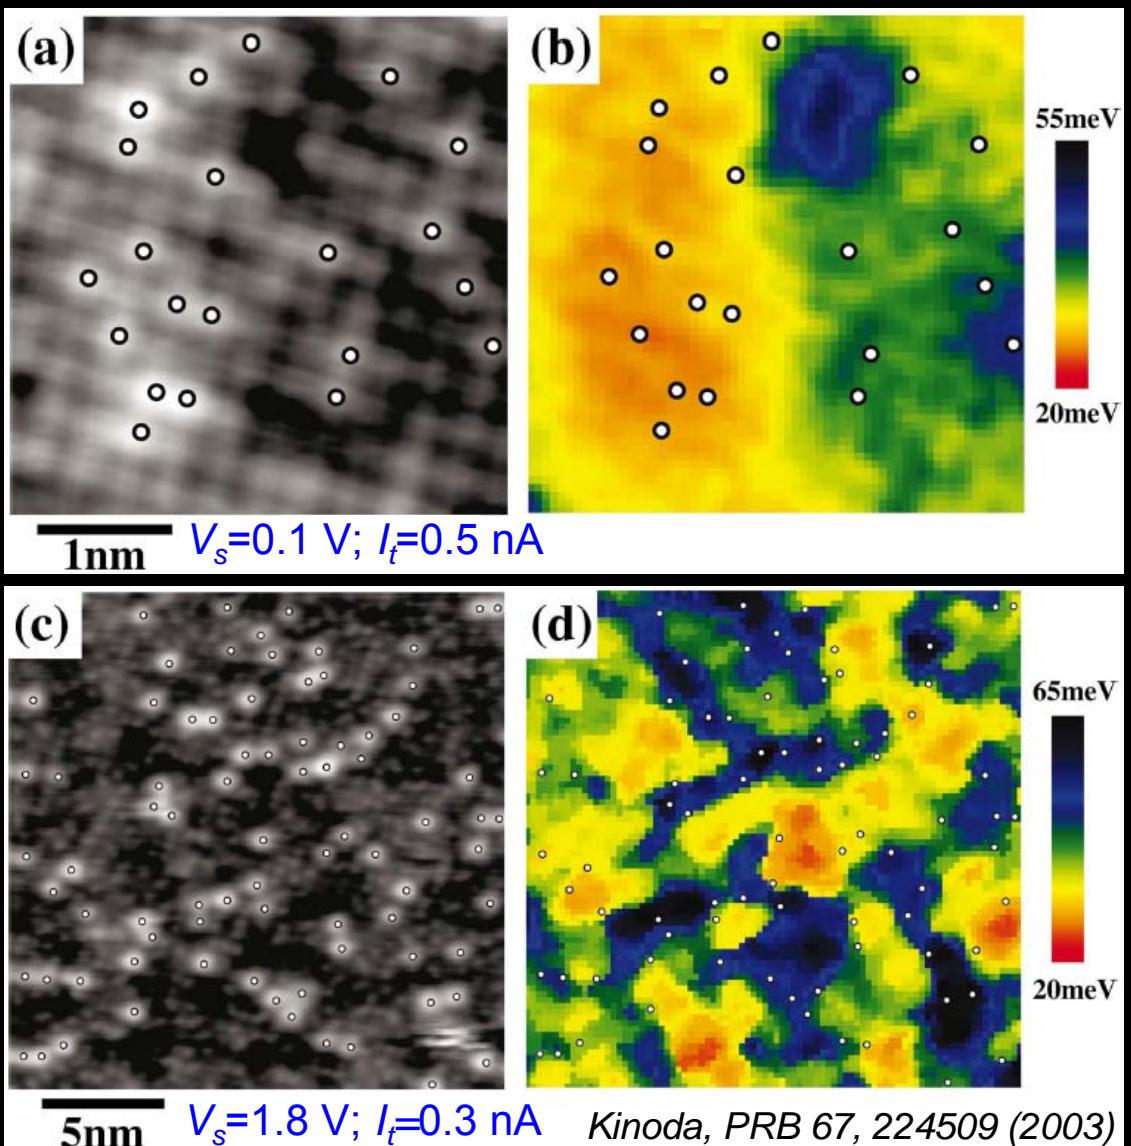

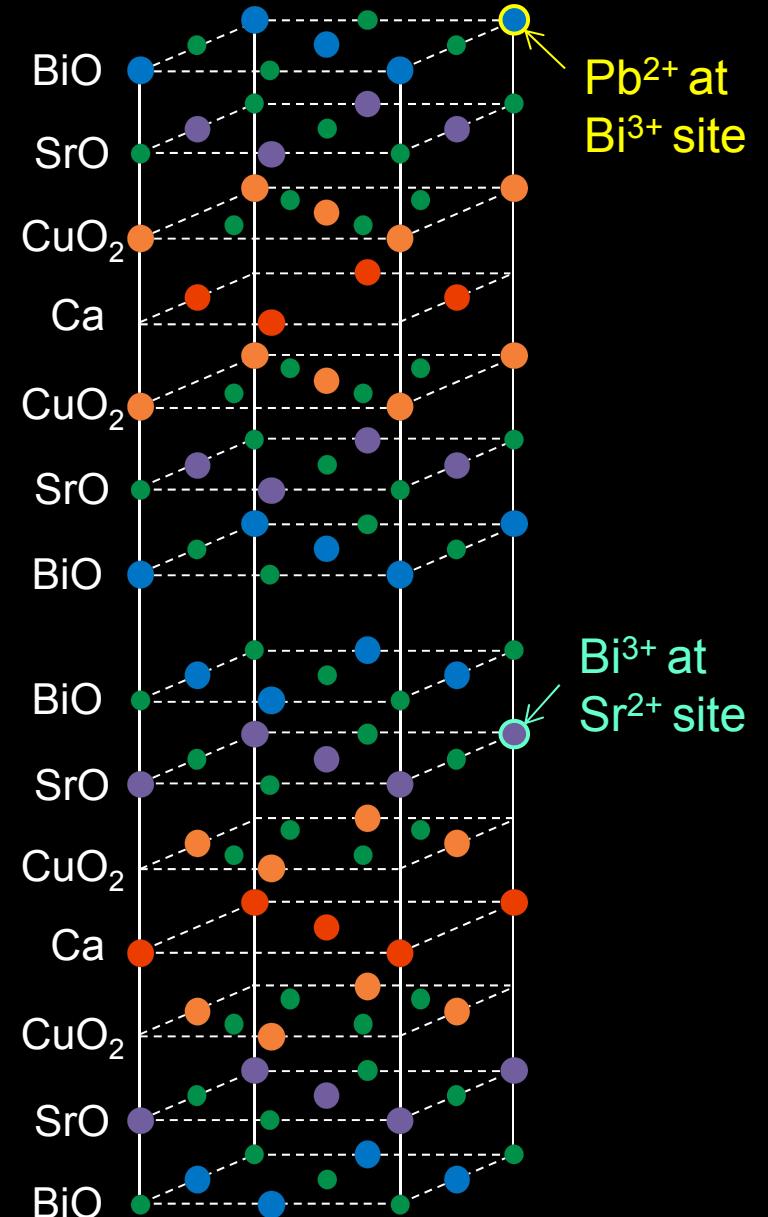

single layer

double layer

triple layer

# Is cation chemistry causing inhomogeneity?

→ Conclude: no correlation between Pb/Bi/Sr substitutions & local  $\Delta$

# Are oxygen dopants causing inhomogeneity?

Conclusions about interstitial oxygen:

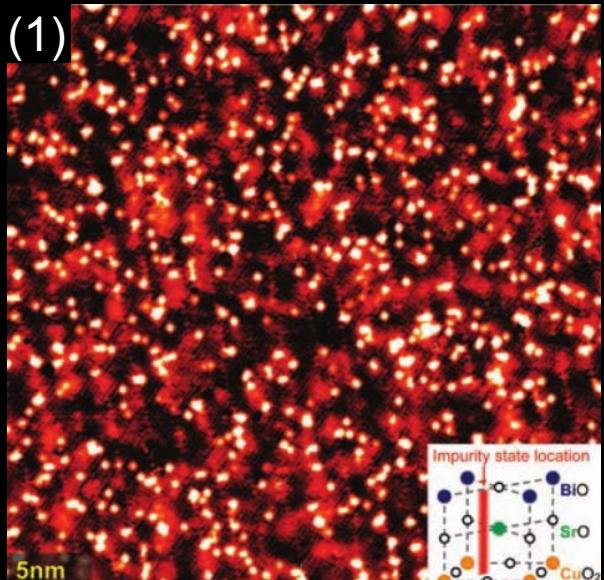

(1) Observed at -0.96 V in  $dI/dV$

(2) “Strong correlations” exist between these oxygen dopants and “the gap”

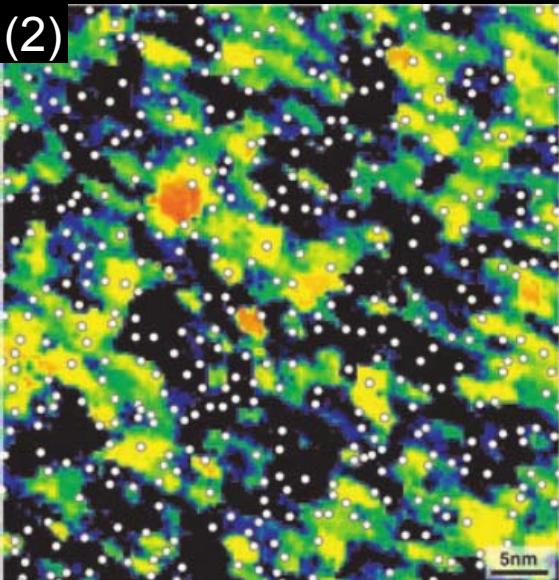

(3) These oxygen dopants are primarily positioned in the minima of the “QPI”

McElroy, *Science* 309, 1048 (2005)

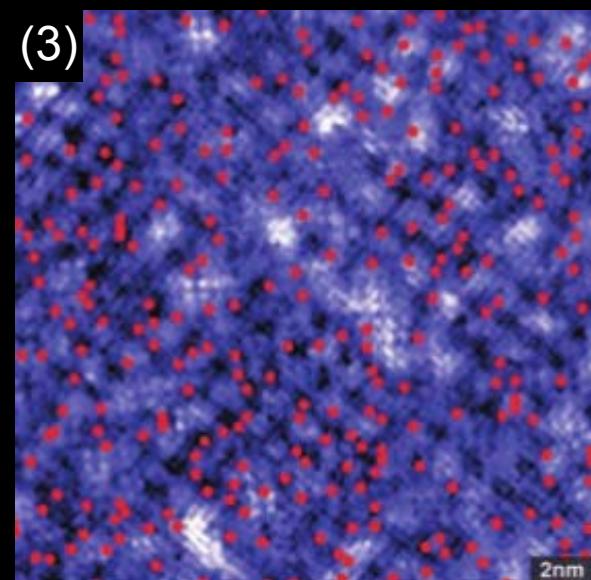

$dI/dV$  at -1V

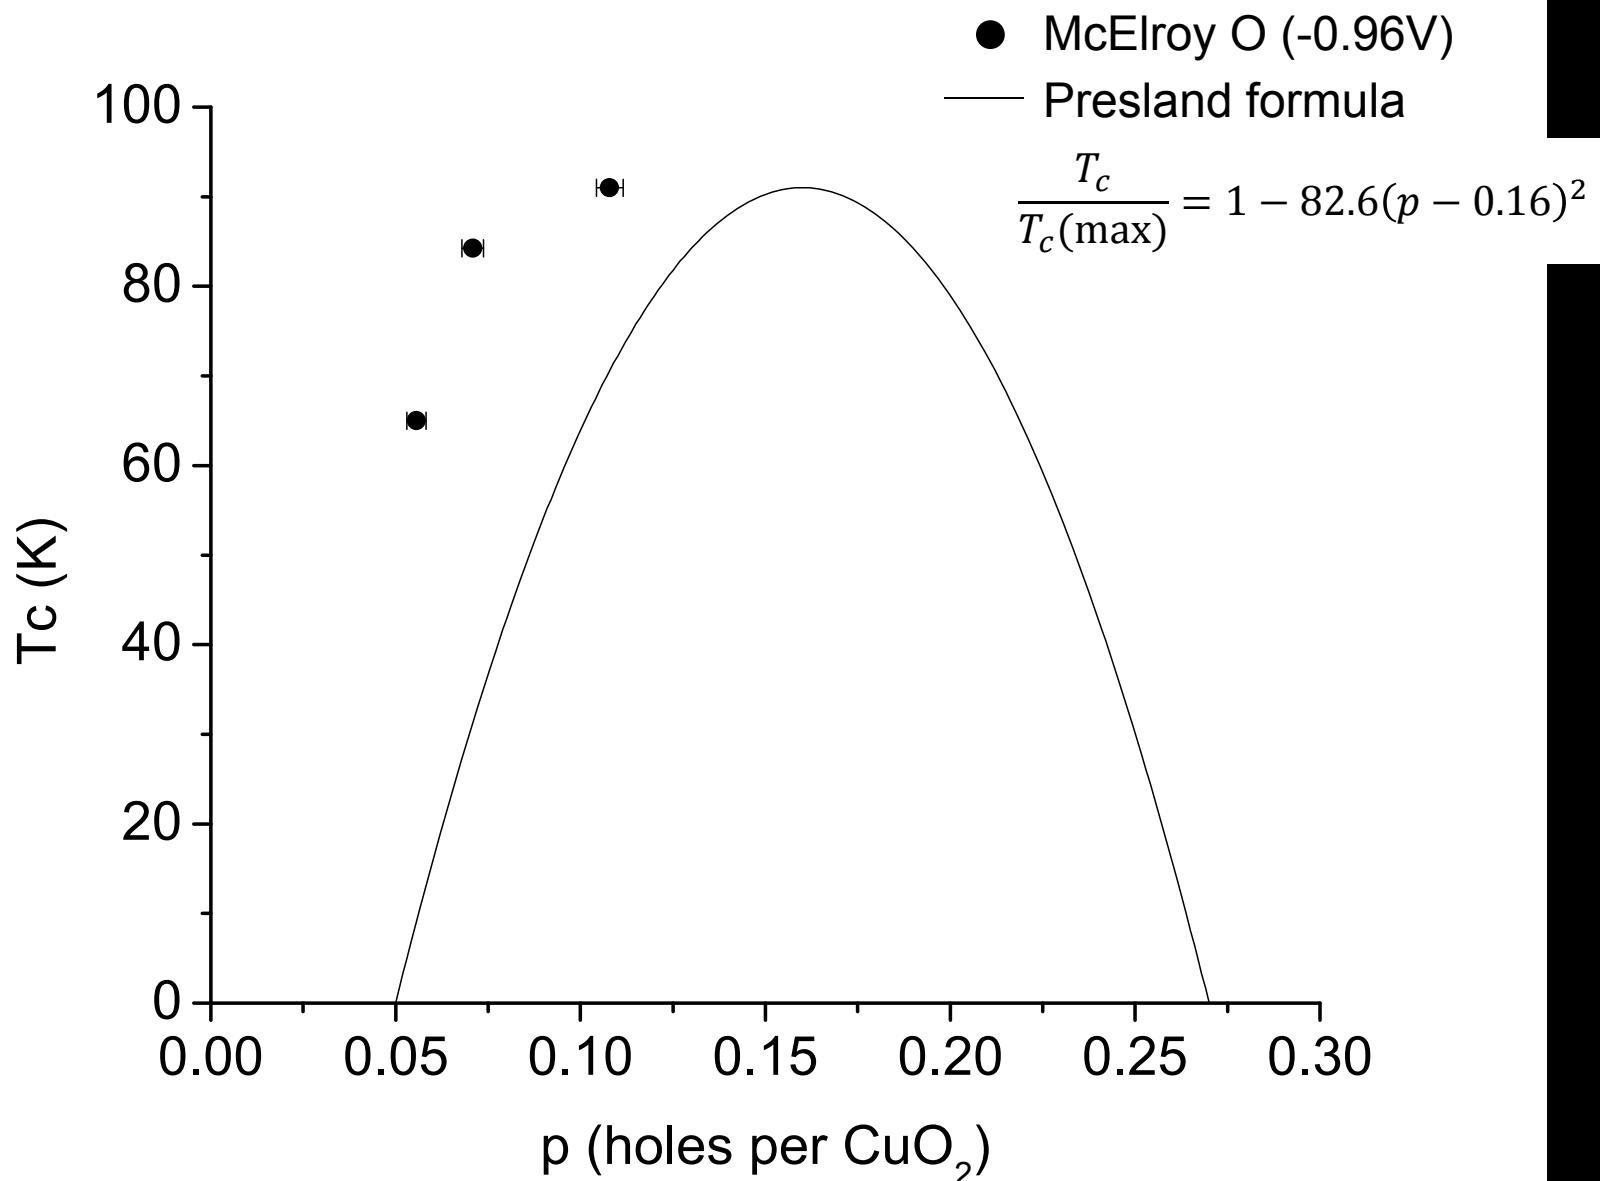

gapmap

$dI/dV$  at -24 mV

# Puzzle 1: too few O dopants

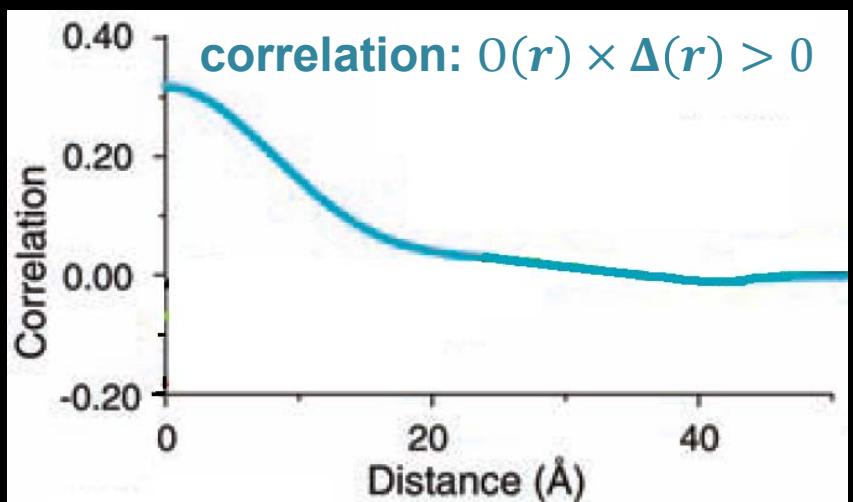

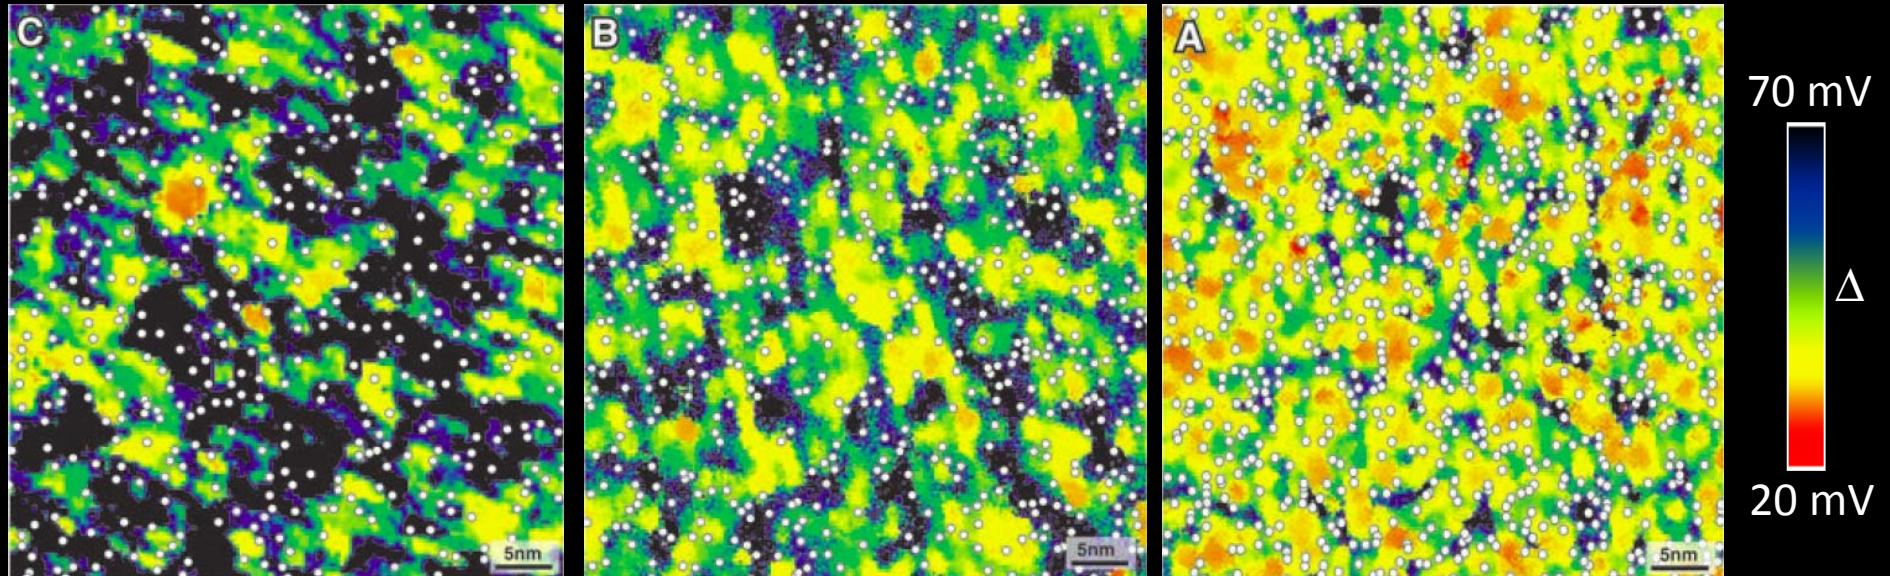

# Puzzle 2: local trend opposes global trend

$\bar{\Delta} = 65 \text{ meV}; N=455$

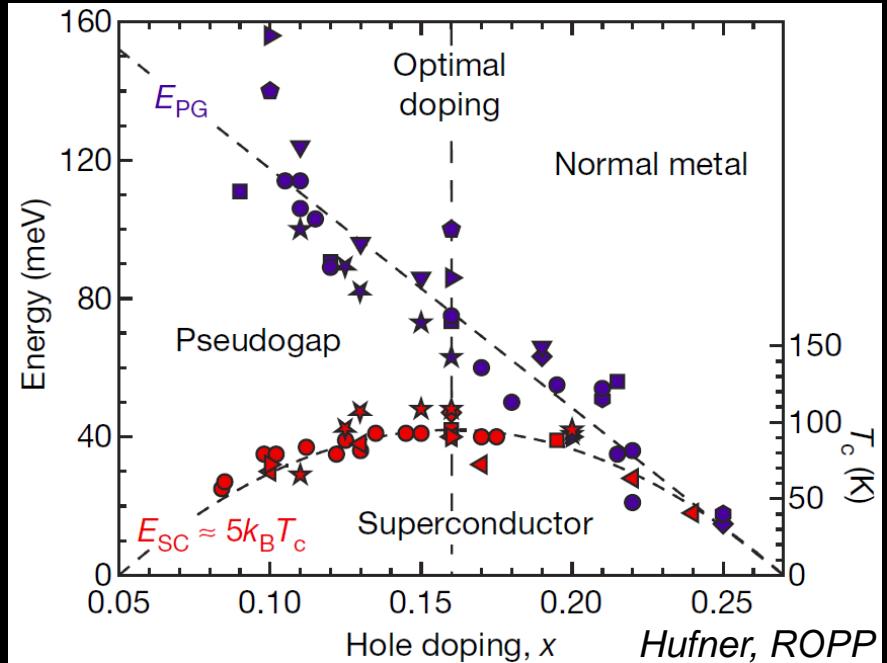

$\bar{\Delta} = 55 \text{ meV}; N=580$

$\bar{\Delta} = 45 \text{ meV}; N=883$

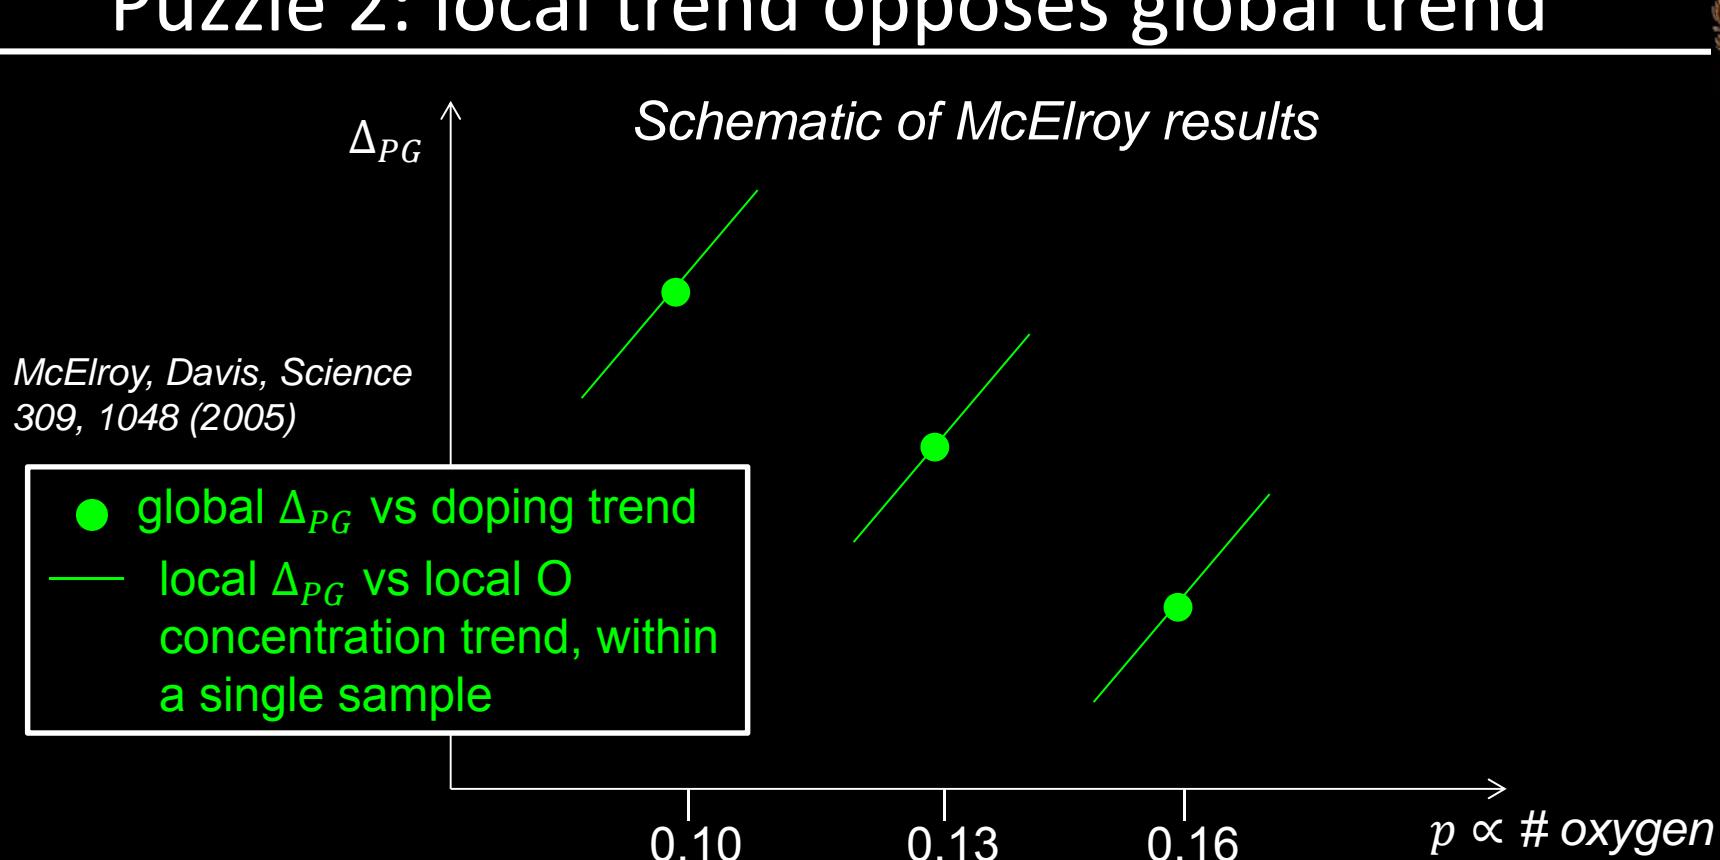

McElroy, Science 309, 1048 (2005)

→ Assumption: oxygen dopants **cause** local regions of large  $\Delta$

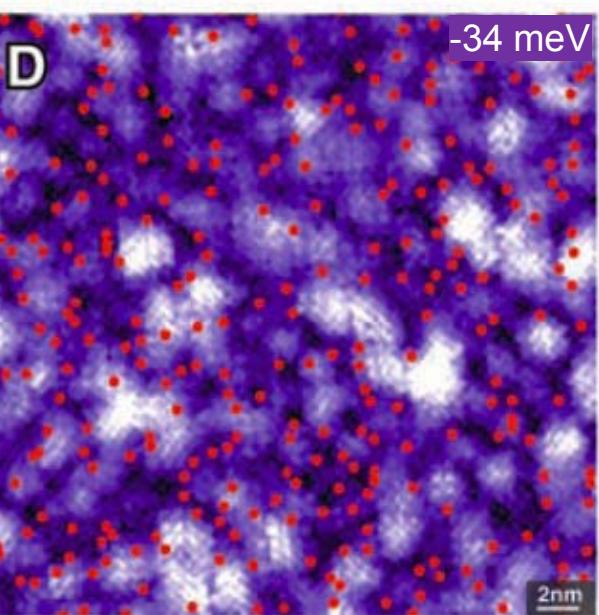

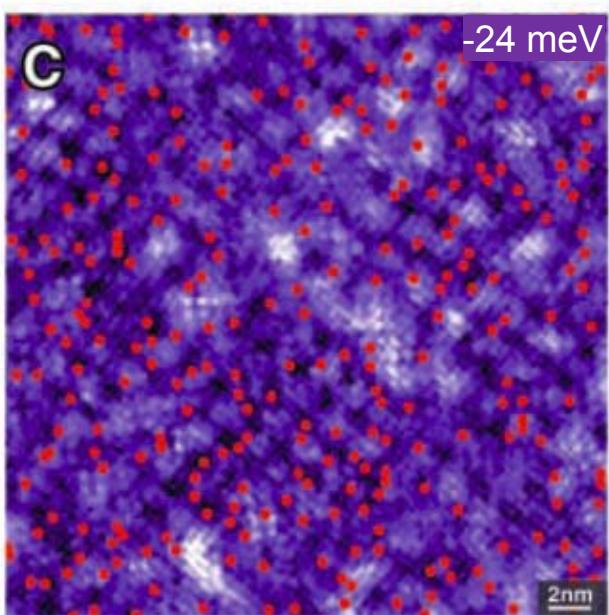

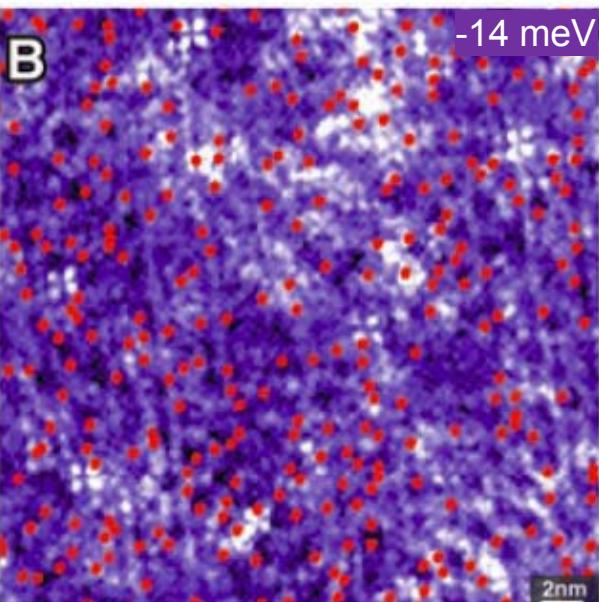

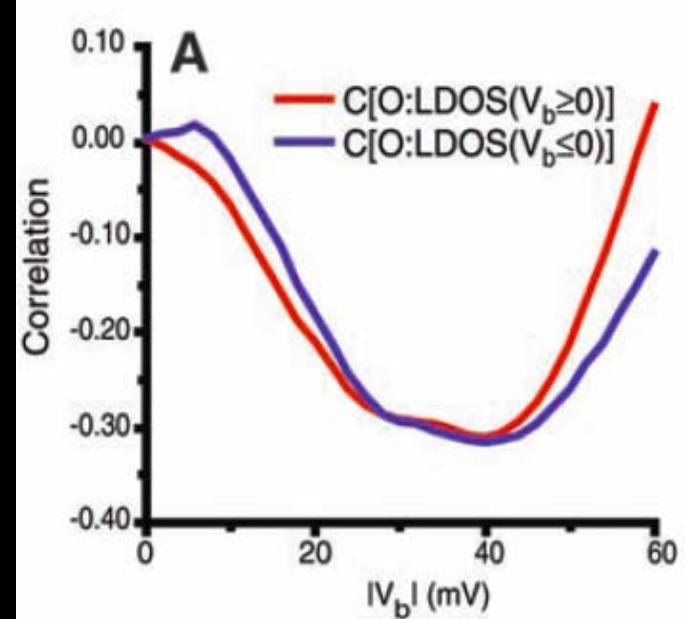

# Puzzle 2: local trend opposes global trend

Many attempts to explain **causality**, focusing on local strain:

- O → local strain, increases local superexchange  $J(\vec{r})$ , locally strengthens pairing  
*Nunner, Hirschfeld, PRL 95, 177003 (2005)*
- experiment: local strain of supermodulation controls the pseudogap  
*Slezak, Davis, PNAS 105, 3203 (2008)*
- O → accumulates local holes, must include phenomenological increase of pairing strength near the dopants, with specific length scale  $0.5a_0$ , to match the data  
*Chen, Hirschfeld, NJP 14, 033004 (2012)*

# Problem 3: relation to QPI

Dopants seem to chase away the low energy states.

Both filled & empty!

But QPI has spatial phase flip across  $E_F$

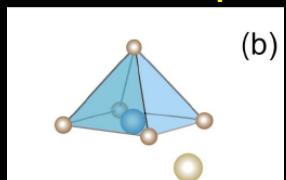

→ this anticorrelation must concern the static checkerboard, not the dispersion QPI

# Zhou prediction: type-A oxygen

B-site disorder:

(e.g.  $\text{Pb}^{2+}$  on  $\text{Bi}^{3+}$  site  
or  $\text{Y}^{3+}$  on  $\text{Ca}^{2+}$  site)

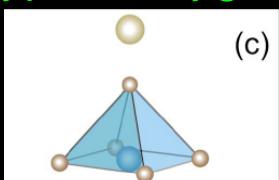

does not couple to  $\text{CuO}_2$

(b)

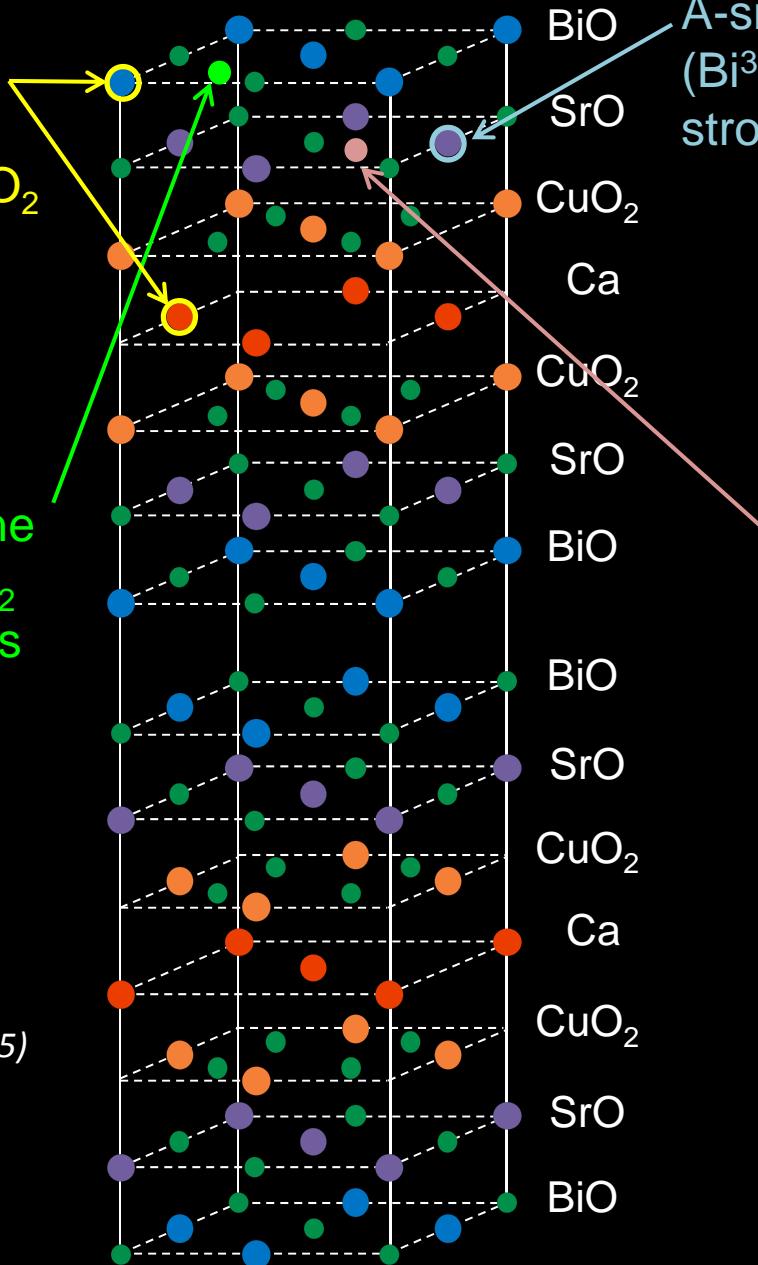

Eisaki, PRB 69, 064512 (2004)

interstitial O in  $\text{BiO}$  plane  
weakly couples to  $\text{CuO}_2$   
provides charge carriers  
but little local effect  
→ “type-B oxygen”

seen at -0.96V

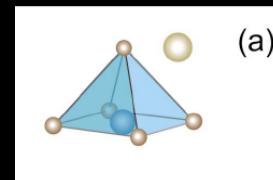

McElroy, Science 309, 1048 (2005)

A-site disorder:

( $\text{Bi}^{3+}$  on  $\text{Sr}^{2+}$  site)

strongly couples to apical O

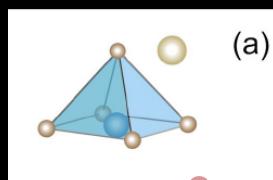

(a)

claim: seen at +1.8V

Kinoda, PRB 67, 224509 (2003)

interstitial O in  $\text{SrO}$  plane  
strongly couples to  $\text{CuO}_2$   
provides charge carriers  
and disorder  
→ “type-A oxygen”

(a)

Zhou, PRL 98, 076401 (2007)

expected << -1V

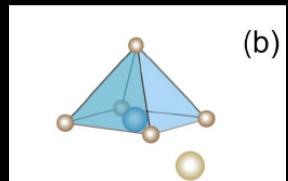

Why is this a problem?

# Zhou prediction: type-A oxygen

B-site disorder:

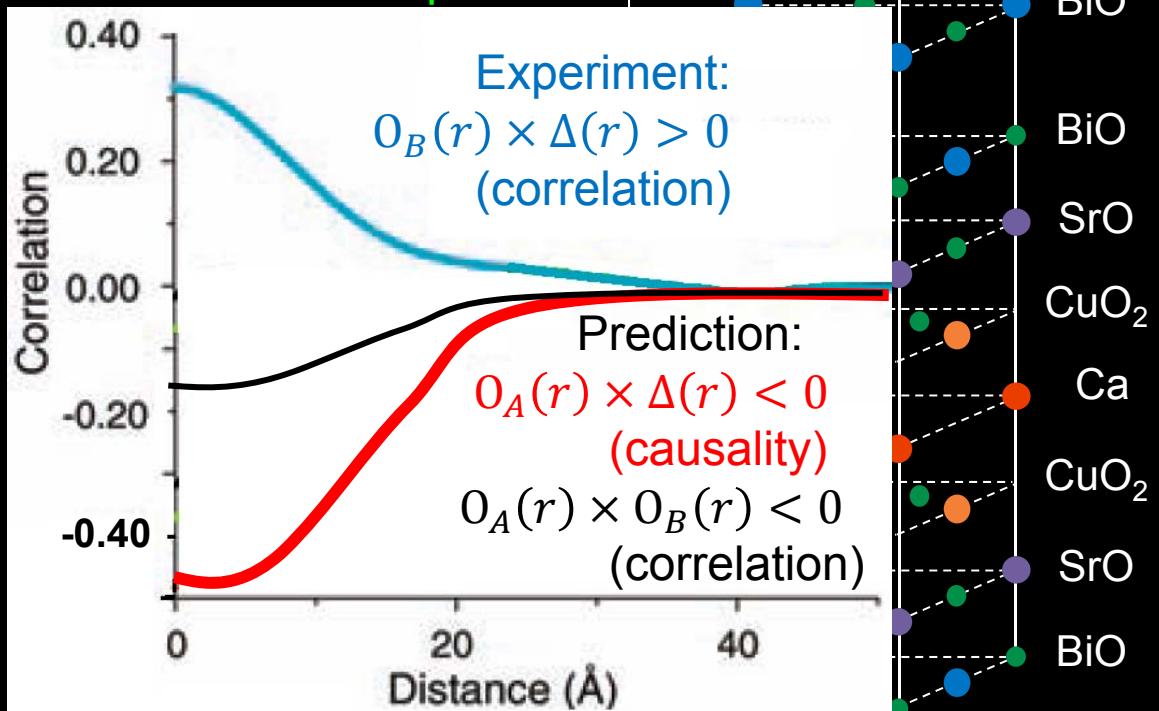

(e.g.  $\text{Pb}^{2+}$  on  $\text{Bi}^{3+}$  site  
or  $\text{Y}^{3+}$  on  $\text{Ca}^{2+}$  site)

does not couple to  $\text{CuO}_2$

Eisaki, PRB 69, 064512 (2004)

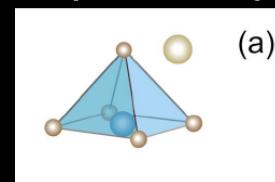

interstitial O in  $\text{BiO}$  plane

A-site disorder:

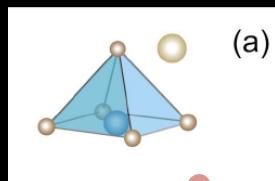

( $\text{Bi}^{3+}$  on  $\text{Sr}^{2+}$  site)

strongly couples to apical O

claim: seen at +1.8V  
 Kinoda, PRB 67, 224509 (2003)

interstitial O in  $\text{SrO}$  plane  
 strongly couples to  $\text{CuO}_2$   
 provides charge carriers  
 and disorder  
 $\rightarrow$  “type-A oxygen”

Zhou, PRL 98, 076401 (2007)

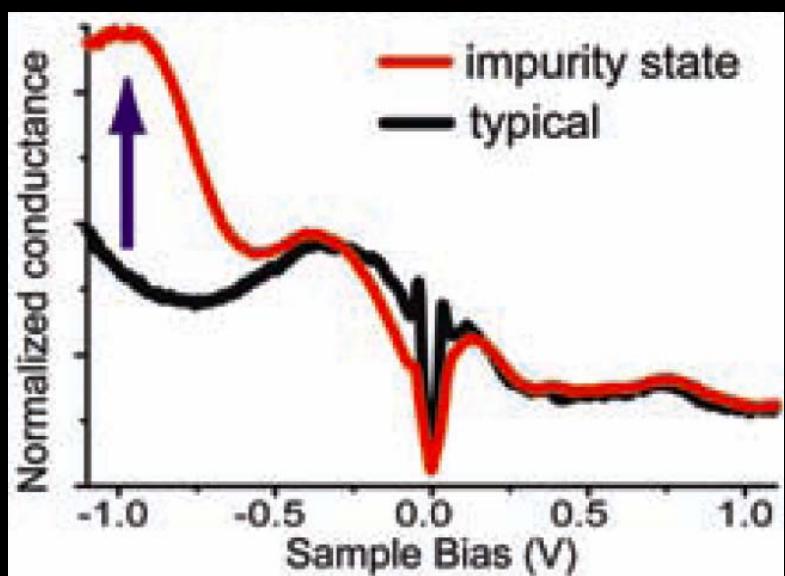

expected  $<< -1\text{V}$

Why is this a problem?

# “High” tip-sample bias

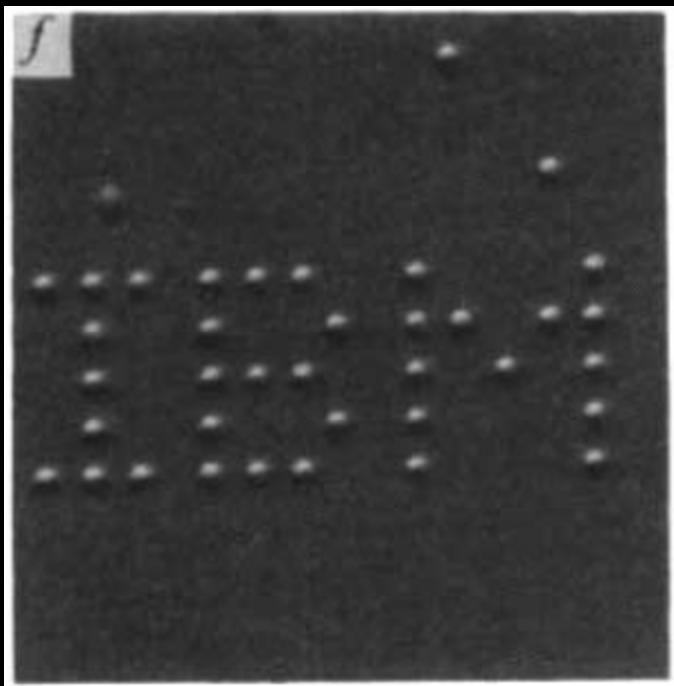

Need to access energies > 1V → Why is this hard?

Highest bias spectroscopy to date  
on BSCCO

McElroy, *Science* 309, 1048 (2005)

What kinds of things happen if one applies higher tip-sample bias?

D. M. Eigler & E. K. Schweizer  
*Nature* 344, 524 (1990)

- move Xe atoms on Ni(110) surface
- using tip-sample bias as low as 0.01 V

# What about that weird local vs. global dependence?

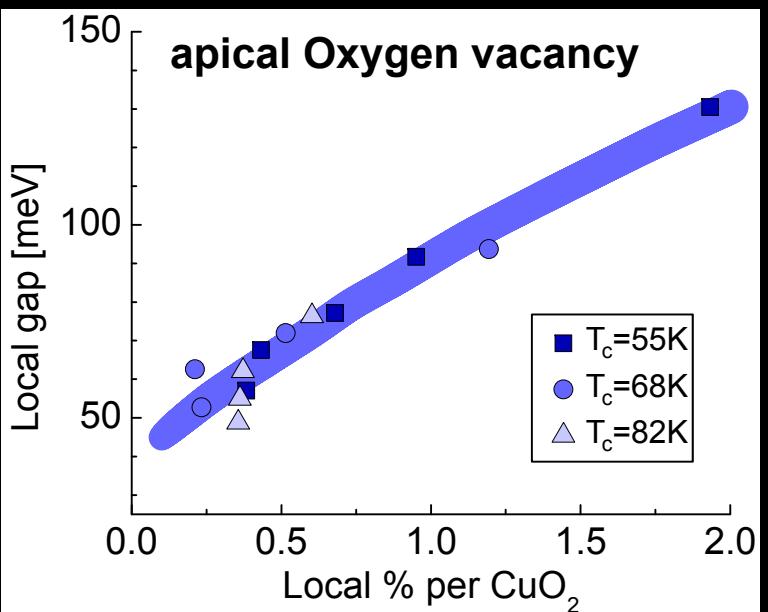

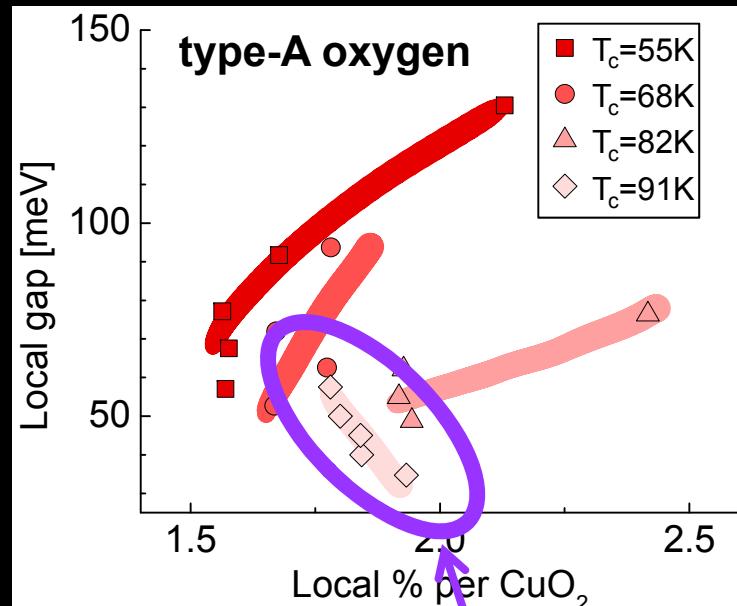

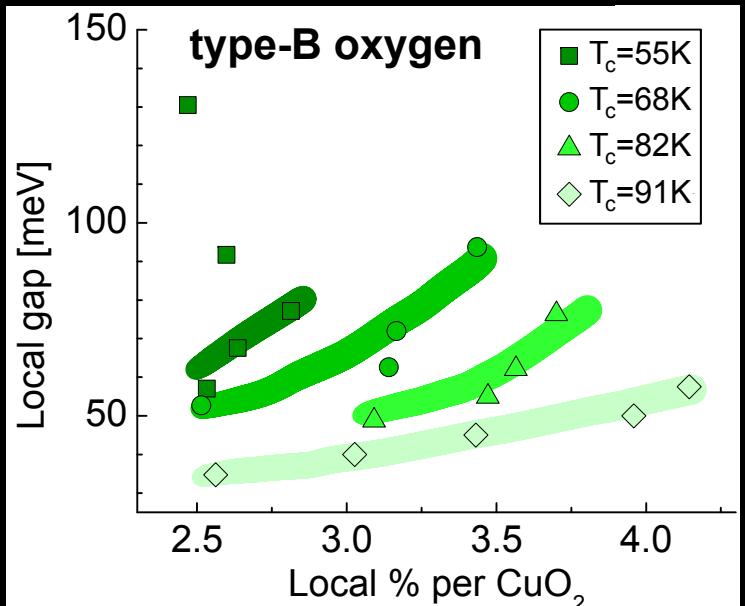

Many explanation attempts, focusing on local strain:

- O → local strain, increases local superexchange  $J(\vec{r})$ , locally strengthens pairing  
*Nunner, Hirschfeld, PRL 95, 177003 (2005)*
- local strain of supermodulation controls the pseudogap  
*Slezak, Davis, PNAS 105, 3203 (2008)*
- O → accumulates local holes, must include phenomenological increase of pairing strength near the dopants, with specific length scale  $0.5a_0$ , to match the data  
*Chen, Hirschfeld, NJP 14, 033004 (2012)*

# What about that weird local vs. global dependence?

# Resolved! local vs. global dependence

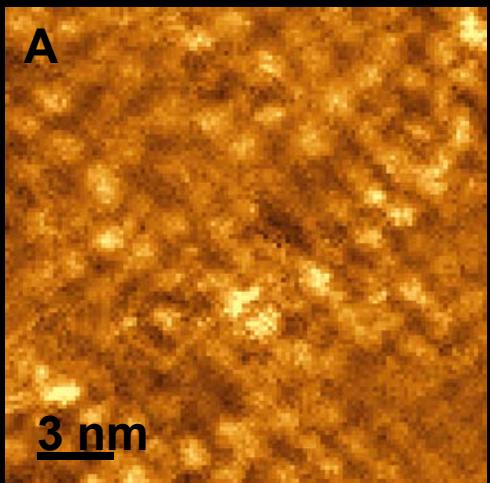

Optimal doping:  
no apical O vacancies

→ local charge controlled  
by type-A interstitial O

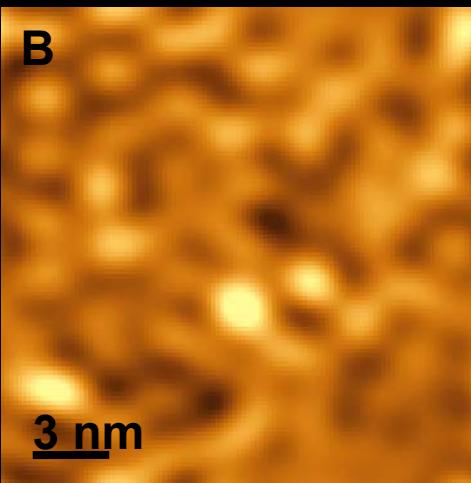

# Determining the relationship to “checkers”

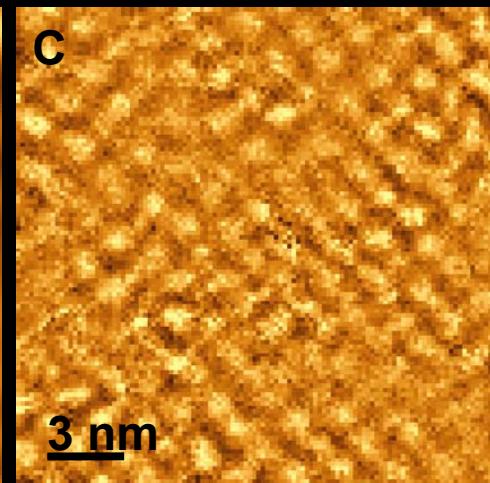

(1) raw data:  $dI/dV$  at +21mV

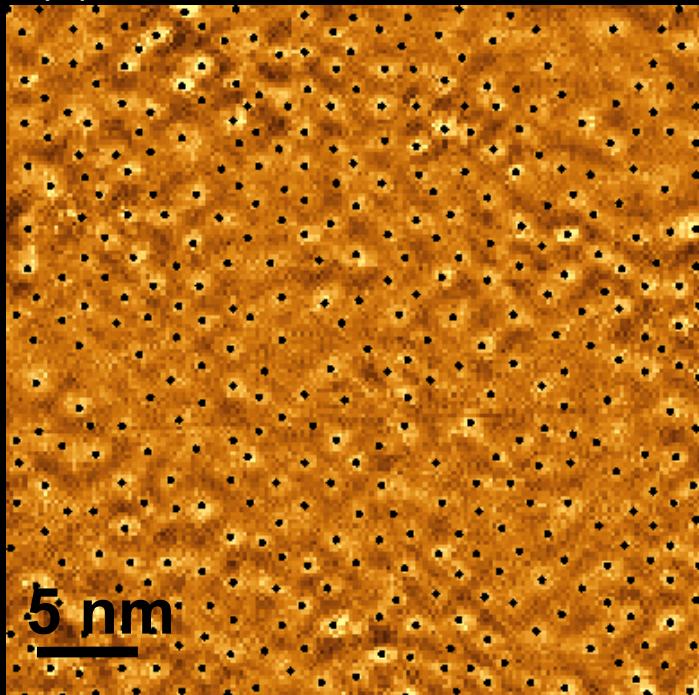

(2) wavelength >  $10a_0$

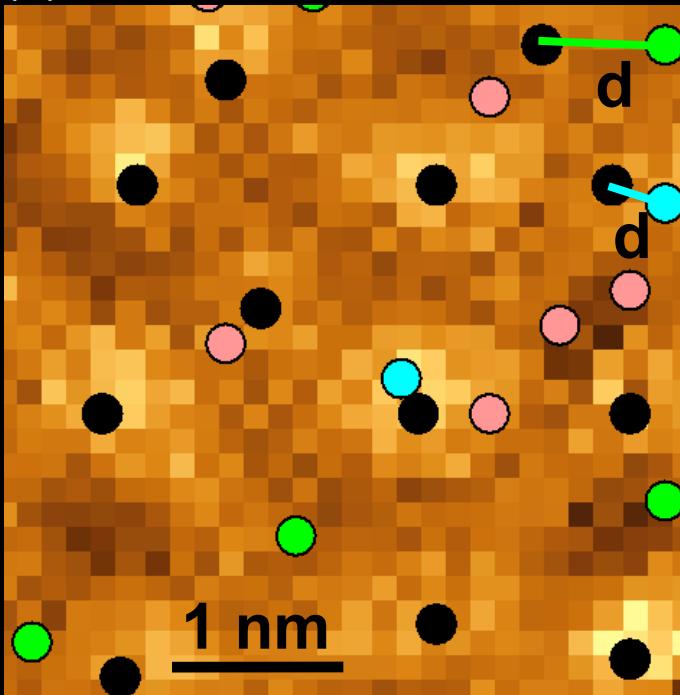

(3) divide:  $C = A/B$

(4) locate all checker maxima

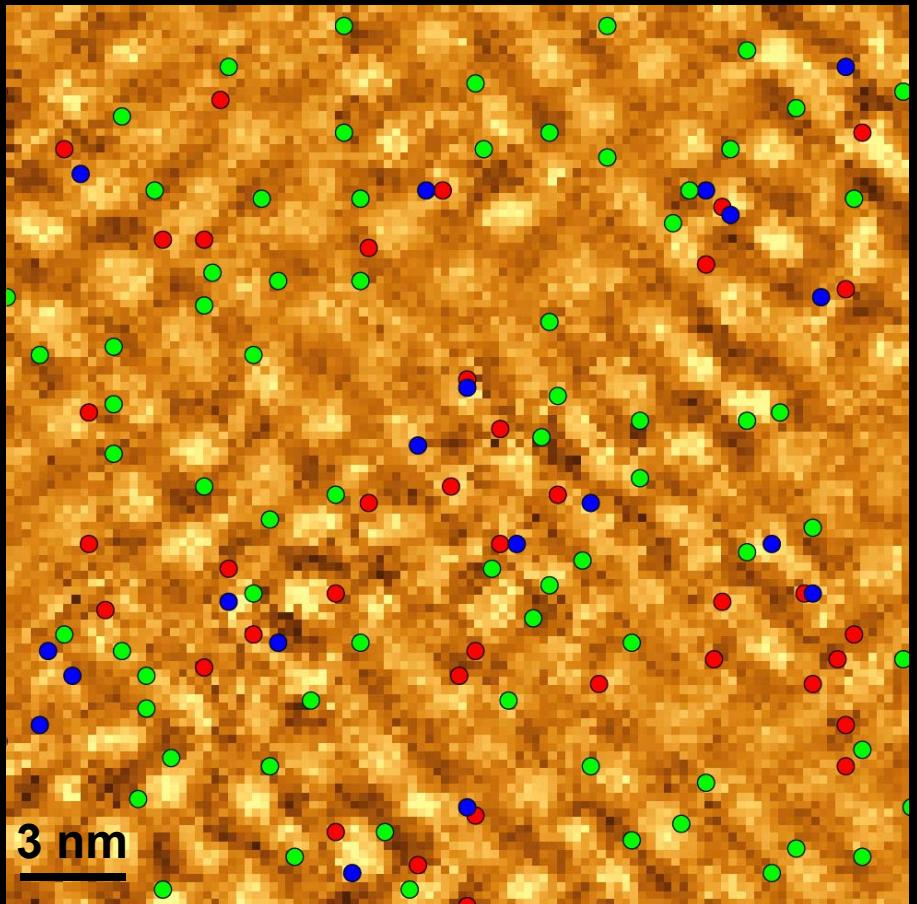

(5) distance to nearest maximum

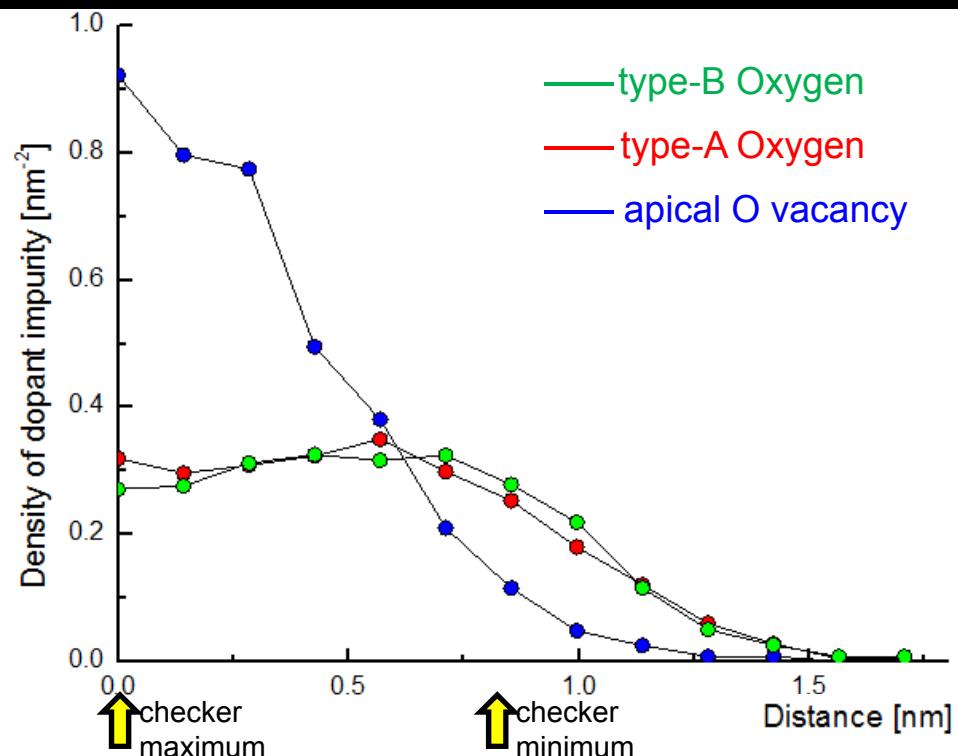

# “Checkers” are pinned by dopants

$V = +24 \text{ mV}$

Low  High

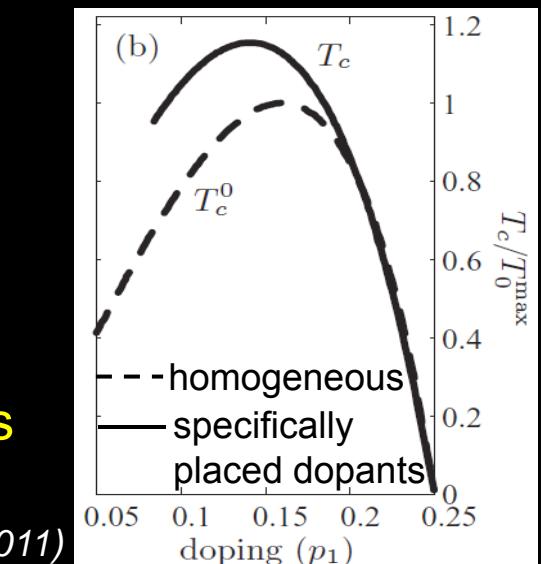

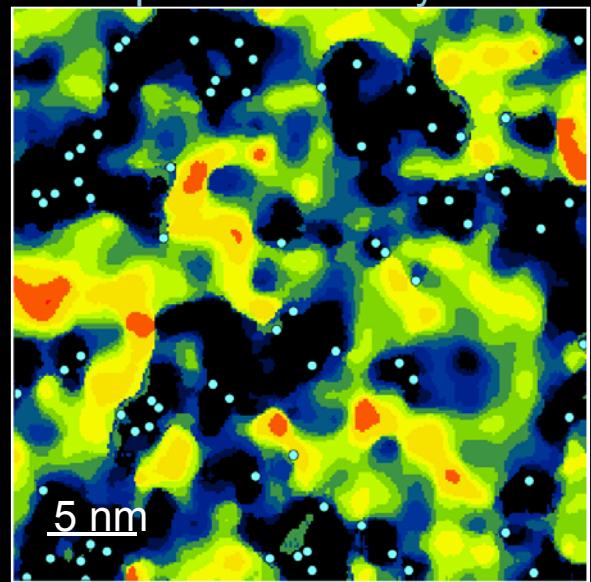

# Part I: Conclusions

- Doubled the energy range for local spectroscopy on BSCCO
- Found all oxygen dopants: type-A & B oxygen, apical O vacancies
- apical O vacancies
  - strongly enhance the pseudogap energy
  - pin the “checkers” charge order

$$k_B T_c = 1.13 \hbar \omega_D e^{\frac{-1}{N(\varepsilon_F)V}}$$

- type-A oxygens
  - attracted to apical O vacancies in UD
  - control local charge in OPT
- type-B oxygens
  - weakly correlate, secondary effect

*To appear in Science (2012)*

Next steps:

- control dopants to raise  $T_c$  ??
- fit to find effective charge & radius of dopants
- understand how dopants affect stripes vs. checkers
